- How to Relax During Search
- Conclusion

Motivation

- → "Relax"ing is a methodology to construct heuristic functions.
 - You can use it when programming a solution to some problem you want/need to solve.
 - Planning systems can use it to derive a heuristic function automatically from the planning task description (the PDDL input).
 - Note 1: If the user had to supply the heuristic function by hand, then we would lose our two main selling points (generality & autonomy & flexibility & rapid prototyping, cf. → Lecture 1-2).
 - **Note 2:** It can of course be of advantage to give the user the *possibility* to (conveniently) supply additional heuristics. Not covered in this course.

How to Relax Informally

•000

How to Relax Informally

How To Relax:

- You have a problem, \mathcal{P} , whose perfect heuristic h^* you wish to estimate.
- You define a simpler problem, \mathcal{P}' , whose perfect heuristic h'^* can be used to estimate h^*
- \blacksquare You define a transformation, r, that simplifies instances from \mathcal{P} into instances \mathcal{P}' .
- Given $\Pi \in \mathcal{P}$, you estimate $h^*(\Pi)$ by $h'^*(r(\Pi))$.

 \rightarrow Relaxation means to simplify the problem, and take the solution to the simpler problem as the heuristic estimate for the solution to the actual problem.

How to Relax During Search

Relaxation in Route-Finding

Motivation

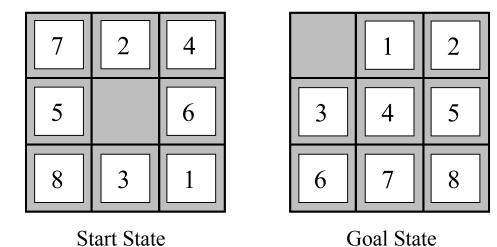

0

How to derive straight-line distance by relaxation?

- Problem P: Route finding.
- Simpler problem \mathcal{P}' : Route finding for birds.
- Perfect heuristic h'^* for \mathcal{P}' : Straight-line distance.
- Transformation r: Pretend you're a bird.

Relaxation in the 8-Puzzle

Perfect heuristic h^* for \mathcal{P} : Actions = "A tile can move from square A to square B if A is adjacent to B and B is blank."

- How to derive the Manhattan distance heuristic? \mathcal{P}' : Actions = "A tile can move from square A to square B if A is adjacent to B."
- How to derive the misplaced tiles heuristic? \mathcal{P}' : Actions = "A tile can move from square A to square B."
- h'^* (resp. r) in both: optimal cost in \mathcal{P}' (resp. use different actions).
- Here: Manhattan distance = 18, misplaced tiles = 8.

"Goal-Counting" Relaxation in Australia

- Propositions P: at(x) for $x \in \{Sy, Ad, Br, Pe, Da\}$; v(x) for $x \in \{Sy, Ad, Br, Pe, Da\}$.
- Actions $a \in A$: drive(x, y) where x, y have a road; $pre_a = \{at(x)\}$, $add_a = \{at(y), v(y)\}$, $del_a = \{at(x)\}$.
- Initial state I: at(Sy), v(Sy).
- Goal G: at(Sy), v(x) for all x.

Let's "act as if we could achieve each goal directly":

- Problem \mathcal{P} : All STRIPS planning tasks.
- Simpler problem \mathcal{P}' : All STRIPS planning tasks with empty preconditions and deletes.
- Perfect heuristic h'^* for \mathcal{P}' : Optimal plan cost $(=h^*)$.
- Transformation r: Drop the preconditions and deletes.
- Heuristic value here? 4.
- → Optimal STRIPS planning with empty preconditions and deletes is still **NP**-hard! (Reduction from MINIMUM COVER, of goal set by add lists.)
- \rightarrow Need to approximate the perfect heuristic h'^* for \mathcal{P}' . Hence goal counting: just approximate h'^* by number-of-false-goals.

- The definition on the next slide is not to be found in any textbook, and not even in any paper.
- Methods generating heuristic functions differ widely, and it is quite difficult (impossible?) to make one definition capturing them all in a natural way.
- Nevertheless, a formal definition is useful to state precisely what are the relevant distinction lines in practice.
- The present definition does, I think, do a rather good job of this.
 - \rightarrow It nicely fits what is currently used in planning.
 - \rightarrow It is flexible in the distinction lines, and it captures the basic construction, as well as the essence of all relaxation ideas.

Motivation

Relaxations

Definition (Relaxation). Let $h^*: \mathcal{P} \mapsto \mathbb{R}_0^+ \cup \{\infty\}$ be a function. A relaxation of h^* is a triple $\mathcal{R} = (\mathcal{P}', r, h'^*)$ where \mathcal{P}' is an arbitrary set, and $r : \mathcal{P} \mapsto \mathcal{P}'$ and $h'^* : P' \mapsto \mathbb{R}_0^+ \cup \{\infty\}$ are functions so that, for all $\Pi \in \mathcal{P}$, the relaxation heuristic $h^{\mathcal{R}}(\Pi) := h'^*(r(\Pi))$ satisfies $h^{\mathcal{R}}(\Pi) \leq h^*(\Pi)$. The relaxation is: native if $\mathcal{P}' \subseteq P$ and $h'^* = h^*$;

- \blacksquare efficiently constructible if there exists a polynomial-time algorithm that, given $\Pi \in \mathcal{P}$, computes $r(\Pi)$;
- efficiently computable if there exists a polynomial-time algorithm that, given $\Pi' \in \mathcal{P}'$, computes $h'^*(\Pi')$.

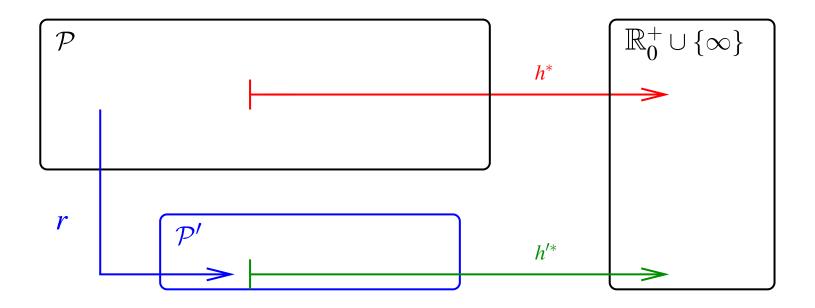

Reminder:

- You have a problem, \mathcal{P} , whose perfect heuristic h^* you wish to estimate.
- You define a simpler problem, \mathcal{P}' , whose perfect heuristic h'^* can be used to (admissibly!) estimate h*
- You define a transformation, r, from \mathcal{P} into \mathcal{P}' .
- Given $\Pi \in \mathcal{P}$, you estimate $h^*(\Pi)$ by $h'^*(r(\Pi))$.

Conclusion

Relaxations: Illustration

Motivation

How to Relax Formally

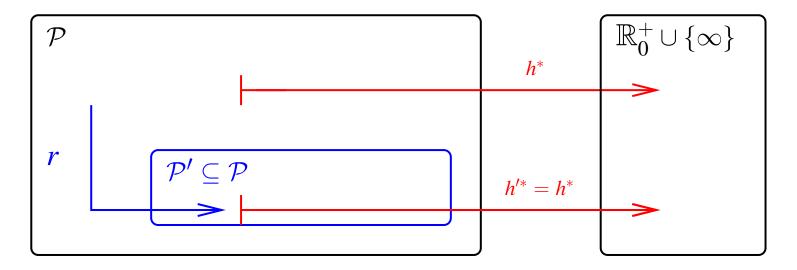

0000000

Example route-finding:

- **Problem** \mathcal{P} : Route finding.
- Simpler problem \mathcal{P}' : Route finding for birds.
- Perfect heuristic h'^* for \mathcal{P}' : Straight-line distance.
- Transformation *r*: Pretend you're a bird.

Native Relaxations: Illustration

Motivation

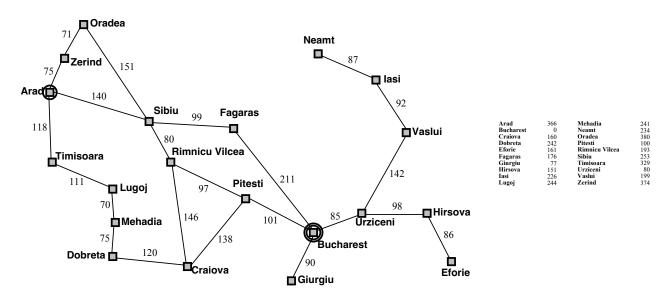

Example "goal-counting":

- Problem \mathcal{P} : All STRIPS planning tasks.
- Simpler problem \mathcal{P}' : All STRIPS planning tasks with empty preconditions and deletes.
- Perfect heuristic h'^* for \mathcal{P}' : Optimal plan cost = h^* .
- Transformation *r*: Drop the preconditions and deletes.

Relaxation in Route-Finding: Properties

0000

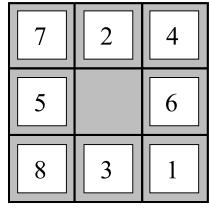

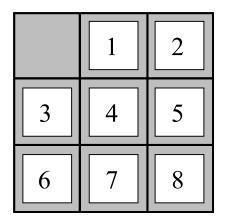

Relaxation $\mathcal{R} = (\mathcal{P}', r, h'^*)$: Pretend you're a bird.

- Native? No: Birds don't do route-finding. (Well, it's equivalent to trivial maps with direct routes between everywhere.)
- Efficiently constructible? Yes (pretend you're a bird).
- Efficiently computable? Yes (measure straight-line distance).

How to Relax Informally

0000

Start State Goal State

Relaxation $\mathcal{R} = (\mathcal{P}', r, h'^*)$: Use more generous actions rule to obtain Manhattan distance.

- Native? No: With the modified rules, it's not the "same puzzle" anymore. (Well, one could be generous in defining what the "same puzzle" is.)
- Efficiently constructible? Yes (exchange action set).
- Efficiently computable? Yes (count misplaced tiles/sum up Manhattan distances).

Motivation

0

What shall we do with the relaxation?

What if \mathcal{R} is not efficiently constructible?

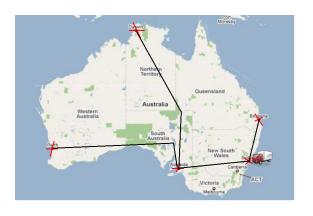

- \blacksquare Either (a) approximate r, or (b) design r in a way so that it will typically be feasible, or (c) just live with it and hope for the best.
- Vast majority of known relaxations (in planning) are efficiently constructible.

What if \mathcal{R} is not efficiently computable?

- Either (a) approximate h'^* , or (b) design h'^* in a way so that it will typically be feasible, or (c) just live with it and hope for the best.
- Many known relaxations (in planning) are efficiently computable, some aren't. The latter use (a); (b) and (c) are not used anywhere right now.

Conclusion

"Goal-Counting" Relaxation in Australia: Properties

- Propositions P: at(x) for $x \in \{Sy, Ad, Br, Pe, Da\}$; v(x) for $x \in \{Sy, Ad, Br, Pe, Da\}$.
- Actions $a \in A$: drive(x, y) where x, y have a road; $pre_a = \{at(x)\}$, $add_a = \{at(y), v(y)\}$, $del_a = \{at(x)\}$.
- Initial state I: at(Sy), v(Sy).
- Goal G: at(Sy), v(x) for all x.

Relaxation $\mathcal{R} = (\mathcal{P}', r, h'^*)$: Remove preconditions and deletes, then use h^* .

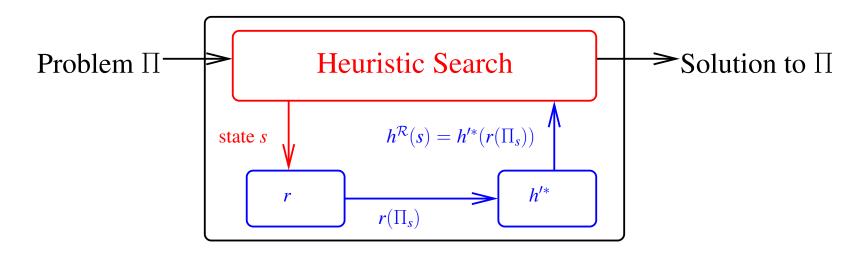

- Native? Yes: Planning with empty preconditions and deletes is a special case of planning (i.e., a sub-class of \mathcal{P}).
- Efficiently constructible? Yes (drop preconditions and deletes).
- Efficiently computable? No! Optimal planning is still NP-hard in this case (MINIMUM COVER of goal set by add lists).

What shall we do with the relaxation? \rightarrow Use method (a): Approximate h^* in \mathcal{P}' by counting the number of goals not currently true.

How to Relax During Search: Diagram

0000

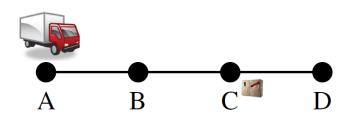

Using a relaxation $\mathcal{R} = (\mathcal{P}', r, h'^*)$ during search:

- $\rightarrow \Pi_s$: Π with initial state replaced by s, i.e., $\Pi = (F, A, c, I, G)$ changed to (F, A, c, s, G).
- \rightarrow The task of finding a plan for search state s.
- → We will be using this notation in the course!

Motivation

Conclusion

Question!

Say we have a robot with one gripper, two rooms A and B, and n balls we must transport. The actions available are moveXY, pickB and dropB; say h ="number of balls not yet in room B". Can h be derived as $h^{\mathcal{R}}$ for a relaxation \mathcal{R} ?

(A): No.

(C): Sure, *every* admissible *h* can be derived via a relaxation.

(D): I'd rather relax at the beach.

 \rightarrow We can define \mathcal{P}' as the problem of computing the cardinality of a finite set, and define r as the function that maps a state to the set of balls not yet in room B. So: (A) is incorrect, (B) is incorrect, should drop preconditions and deletes.

 \rightarrow (C): Yes. Admissibility of $h^{\mathcal{R}}$ is the only strict requirement made by the definition. Given admissible $h: \mathcal{P} \mapsto \mathbb{R}_0^+ \cup \{\infty\}$, we can simply define $\mathcal{P}':=\mathcal{P}$ and take r to be the identity function $id_{\mathcal{P}}$. In other words, $\mathcal{R} := (\mathcal{P}, id_{\mathcal{P}}, h)$ is a relaxation with $h^{\mathcal{R}} = h$. (And, yes, h here is admissible.)

Summary

Relaxation is a method to compute heuristic functions.

How to Relax Informally

- Given a problem \mathcal{P} we want to solve, we define a relaxed problem \mathcal{P}' . We derive the heuristic by mapping into \mathcal{P}' and taking the solution to this simpler problem as the heuristic estimate.
- Relaxations can be native, efficiently constructible, and/or efficiently computable. None of this is a strict requirement to be useful.
- During search, the relaxation is used only inside the computation of the heuristic function on each state; the relaxation does not affect anything else. (This can be a bit confusing especially for native relaxations like ignoring deletes.)

Remarks

The goal-counting approximation h = "count the number of goals currently not true" is a very uninformative heuristic function:

How to Relax Formally

0000000

- Range of heuristic values is small (0...|G|).
- We can transform any planning task into an equivalent one where h(s) = 1 for all non-goal states s. How? Replace goal by new fact g and add a new action achieving g with precondition G.
- Ignores almost all structure: Heuristic value does not depend on the actions at all!
- \rightarrow By the way, is h safe/goal-aware/admissible/consistent? Only safe and goal-aware.
- \rightarrow We will see in \rightarrow the next lecture how to compute **much** better heuristic functions.

Conclusion
